CALIFORNIA AVOCADO SUSTAINABILITY

Calculations and source information for this text on CaliforniaAvocado.com:

“A one-acre avocado grove sequesters up to 2.6 tons of carbon dioxide each year, meaning California Avocado groves help renew their communities’ air supply and keep it fresh.”

Calculations:

- Average number of California Avocado trees per acre = 110*
- 1 single mature tree can absorb carbon dioxide at a rate of 48 pounds per year**
- 110 trees per acre x 48 pounds = 5,280 pounds of carbon dioxide absorbed per acre
- 1 ton = 2000 pounds
- 5,280 pounds/2000 = 2.6 tons

Estimates of the Replacement Costs of Commercial and Backyard Avocado Trees in South Florida

Edward A. Evans and Jonathan H. Crane

Introduction

The Florida avocado industry is the state’s second-largest fruit industry (behind citrus) and is worth $12 to $14 million a year at the farm gate (USDA/NASS 2008) and $30 million at the wholesale level (Brooks, personal communication). The commercial avocado industry in Florida consists of approximately 7,500 acres (60 percent of the total tropical fruit acreage), about 951 growers (USDA/NASS 2008; USDA/NASS 2009; Crane, Balerdi, and Maguire 2007), and 35 registered avocado handlers and shippers (Brooks, personal communication). Of these 7,500 acres, over 98 percent are located in southwest Miami-Dade County. In addition to commercial production, many homeowners in South Florida have backyard avocado trees. These trees form an important part of the urban canopy and contribute economic, aesthetic, and environmental benefits, adding as much as 10 percent to residential property values. They provide shade and wildlife habitat, and improve air quality. As pointed out by McAliney (1993), a single mature tree can absorb carbon dioxide at a rate of 48 pounds per year, and release enough oxygen back into the atmosphere to support two human beings. It is estimated that there are more than 250,000 backyard avocado trees scattered across Miami-Dade County (Pybas, personal communication).

In light of the recent discovery of the redbay-laurel wilt disease complex, which can destroy both commercial and backyard avocado trees (Mayfield et al. 2008), the purpose of this article is to estimate how much it would cost to replace all commercial and residential backyard avocado trees in Miami-Dade, Broward, Palm Beach, and Lee Counties.

Methodology

Although there are several approaches to estimating the replacement cost, the approach adopted in this article is based on compensatory value (Nowak et al. 2002); that is, the value owners should be compensated for the loss of mature avocado trees, based on the principle that avocado trees can be viewed as structural assets. The compensatory value of the trees is calculated using the internet tool Tree Value Analysis (Evans et al. 2006). Calculations are based on the present value of the net costs of replacing lost trees and nurturing replacement trees to the production equivalent of lost trees. Net costs include: (1) the cost of replacing trees (stump removal, land preparation, purchasing and planting new trees); (2) new tree cultivation costs (fertilizer, pruning, weeding) during a replacement period of seven years; and (3) lost revenue from non-bearing trees. Stream of net costs for bringing replacement trees up to the production equivalent of lost trees are discounted to determine the present value of a tree.

Using the tool and inserting a $0.25 per pound farm gate price, the 2007/08 average grower’s price (USDA/NASS 2009), a $150 per tree stump removal cost (Evans 2006),
and a five percent discount rate, we estimate the value of a mature tree to be around $330. This value was used for both commercial and non-commercial avocado trees and does not include any provisions for sentimental values attached to a homeowner’s tree, or the fact that inputs used by the homeowner, including fertilizer and water, could be far more expensive than those used by commercial producers. In the case of commercial orchards, an average of 87 trees per acre was used to estimate the total number of trees in a county (Balerdi, personal communication).

To estimate the total number of backyard trees in Broward, Palm Beach, and Lee Counties, it was assumed that the ratio of backyard trees to population that exists in Miami-Dade County would be the same in these counties. This ratio was then applied to population estimates of these counties as contained in the 2008 United States Census.

**Results**

The table below summarizes the results of the cost analysis. The figures indicate that the total cost to replace all avocado trees in the four counties is $422.8 million. The cost to replace only the commercial trees is estimated at $216.1 million, while the cost for residential backyard trees is $206.7 million. As expected, Miami-Dade County had the highest total replacement cost of $294.9 million, followed by Broward County at $60.5 million.

**Conclusions**

Avocado trees contribute several market (food source, income, and employment) and nonmarket (open space retention, canopy cover, carbon sequestration, and wildlife habitats) benefits. The importance of canopy cover is recognized by the counties as evidenced by the Adopt-A-Tree Program, which has distributed about 13,822 avocado trees to date. Redbay laurel wilt disease complex has spread to South Florida, where the cost to replace avocado trees destroyed by this disease in Miami-Dade, Broward, Palm Beach, and Lee Counties would be about $423 million. As our analysis shows, it is imperative to prevent the spread of this disease in Florida.
